

Here the numbers can either grow or reduce any year depending on the usage of a company's financial assets. In case a company keeps accumulating financial assets, the income growth will be regularly high. If, however, they spend a large chunk of financial assets in a year, the other income growth can decrease. This is a fairly straightforward number derived from the financial assets that the company has.

We need to study other income as a percentage of total financing assets. If we convert the numbers into percentages, we get an idea of how much the company earns from its financial assets.

If the company is earning 5 crores and the total financial assets amount to 50 crores, it is earning a 10% return on it. This shows the percent return a company earns on its total financial assets.

Considering the numbers on the sheet, we see that the company is earning 7.27%, 6.09%, 8.08%, 6.64%, 6.17% of return on financial assets each year respectively. Ideally, the company should not be earning less than the market fixed deposit returns as they are the base amount that can be earned irrespective of the time.
