

vulnerabilities,” Patankar told me. This is critical because a threat can appear out of nowhere – a malicious snippet of code injected into a supposedly benign update, or a cleverly disguised phishing attempt exploiting a user’s trust in a familiar brand.

By maintaining a scalable cloud infrastructure, Protectt.ai can correlate threat intelligence across vast data sets. According to Patankar, “Our scalable cloud infrastructure enables efficient threat intelligence and provides actionable insights to strengthen our clients’ mobile app security posture.”

How Protectt.ai is bridging the mobile app security gap

Downloading apps only from official app stores like Google Play or Apple’s App Store is often the first recommended step towards mobile app safety that we all know. These platforms do perform initial security scans, creating a reliable environment for users. However, even after these apps are downloaded, vulnerabilities can emerge.

“While Play Store and App Store conduct rigorous security checks before publishing apps on their platform, challenges arise after installation,”

Patankar explained. Attackers can reverse-engineer apps, tamper with their code, and repackage them to distribute malicious versions via phishing links. Once installed, these rogue apps can compromise user data or even carry out unauthorized financial transactions.

“This evolving threat landscape requires a proactive approach beyond the initial checks offered by app stores. Protectt.ai addresses this critical gap with AppProtectt, a state-of-the-art solution that continuously monitors apps in real-time, detecting and neutralising dynamic

threats such as malware, reverse engineering, and tampering.” Patankar emphasised. It’s a proactive stance – while stores focus on a one-time approval, Protectt.ai ensures the app remains safe throughout its lifecycle.

When you think of mobile security, the word “antivirus” might come to mind. But as Patankar noted, antivirus solutions mainly target known malware strains. Today’s threats extend much further. Reverse engineering, debugging, root detection bypasses, API manipulation – the list goes on and on.

“AppProtectt provides 75+ security capabilities such as Anti-Malware, Unsecured Wi-Fi, Reverse Engineering, Decompilation, Debugging, Root Detection, App Tampering protection, Screen sharing and Screen Mirroring Fraud Protection.” All of that’s quite a mouthful, but it boils down to a comprehensive, layered defence that doesn’t just check for malware signatures – it watches for anything suspicious happening in the runtime environment.

Patankar summed it up: “While traditional antivirus software covers known malware and viruses, AppProtectt offers multi-layered defence mechanisms tailored to safeguard apps from a wide range of sophisticated mobile security threats.” Few industries exemplify the need for robust mobile security more than BFSI (Banking, Financial Services, and Insurance). With millions of users performing sensitive transactions daily, a single breach can be catastrophic.

Patankar painted a vivid picture: “Our internal research suggests that more than 90% of apps in the BFSI sector are prone to reverse engineering.” That’s staggering, considering how many of us rely on mobile banking apps for everything from checking balances to making mortgage payments.

To drive the point home, he shared a real-world example: “For a leading private sector bank in India with 5+ million users, we implemented our solution. In 3 months, we saw an 87% reduction in screen mirroring cases.” That’s the kind of tangible result that stands out – less theoretical and more like a real-life

intervention that prevents fraud and preserves trust.

AI-driven threat detection in zero trust environment

Looking beyond the present, Patankar predicted emerging scenarios where the complexity of mobile apps would continue to grow. “Super apps are the future, combining multiple services like messaging, payments, shopping, and travel into a single platform,” he said. More functionalities mean broader attack surfaces, reinforcing the need for a robust, adaptive security posture.

AI-driven threat detection, behavioural analytics, and zero trust frameworks are all on the horizon. Patankar was optimistic: “By offering diverse functionalities under one roof, super apps boost user engagement and stickiness... These technologies will help identify and neutralise threats in real-time, often before the user is even aware, by analysing patterns and anomalies in data.”

In other words, tomorrow’s mobile app security won’t just react to threats – it’ll anticipate them. One negative about security solutions is often that they sacrifice user experience for protection. If apps become sluggish or start throwing false positives left and right, users lose patience – and possibly trust.

Patankar addressed this: “Protectt.ai uses deep technology solutions – advanced AI and machine learning to analyse threats. This helps enhance product security capabilities and minimise false positives.”
