

57 organisations join Agentic AI Foundation

The Agentic AI Foundation (AAIF) has added 57 organisations, taking its membership to 247 as enterprises increasingly back open source infrastructure and standards for interoperable AI agents. The new members span financial services, telecommunications, and academia, with Alibaba Group, Visa, and Wells Fargo & Company joining as Gold-tier members after contributing US\$ 200,000 each.

Stewarded by the Linux Foundation (LF), AAIF aims to establish open standards that allow AI agents to work across tools, platforms, systems, and industries. Its growing membership signals enterprise interest in shared infrastructure rather than proprietary agent stacks.

AAIF's open ecosystem includes the Model Context Protocol (MCP), originally introduced by Anthropic, which provides a standard way for AI applications to connect with external tools, systems, and data sources. OpenAI is among its supporters. The foundation also oversees AGENTS.md, originally contributed by OpenAI, which provides instructions and context for coding agents, and Goose, an open modular AI agent framework introduced by Block for building local agentic workflows.

Enterprises can join through Gold, Silver, and Associate tiers, although membership is not required to contribute to AAIF's open source projects.

A single sensor cannot determine a person's exact position, and it is also difficult to distinguish multiple people based on disturbances in the Wi-Fi signals. The project therefore focuses mainly on determining whether a person or another living creature is present in a particular area.

Oracle bans AI-generated contributions to OpenJDK

Oracle has imposed an interim ban on AI-generated contributions to OpenJDK, requiring contributions to “must not include content generated, in part or in full,” by large language models, diffusion models or similar systems. The restriction covers source code, text and images submitted through Git repositories, GitHub pull requests, emails, wikis and issue trackers. AI can still be used privately for understanding, debugging, reviewing and research.

The move exposes a wider open source governance question: should AI provenance disqualify contributions, or should projects focus on human accountability and code quality? Linux permits AI-assisted contributions with disclosure, testing and human sign-off, while LLVM allows them with human review and disclosure. Oracle-owned GraalVM also permits AI-assisted contributions under human responsibility.

Pratik Ambhore, head of data engineering at R Systems, called the ban an interim risk measure rather than a sustainable model, advocating “trust, but validate” through disclosure and human accountability.

Comma.ai launches docks with open source firmware

Comma.ai has launched the Chestnut Dock and Tiny Chestnut eGPU Dock with open source firmware. The firmware is written in C and is available on GitHub, where developers can access the source code and modify the low-level firmware running on the dock. It targets the ASM2464PD USB4/Thunderbolt-to-NVMe bridge controller.

The dock series focuses mainly on increasing computational power for Comma.ai's driving assistance system; however, the Chestnut Dock may connect to a normal computer to use it as a USB4 dock along with supporting Tinygrad applications. In the case of automobiles, these docks are created to enable increased computational power for bigger driving models. Comma.ai claims that the Chestnut Dock expands the available compute power from 10W to up to 100W. The Tiny Chestnut can also be paired with an external AMD Radeon RX 9060 GPU with 8GB of memory.

The open source firmware makes the dock more accessible for developers who want to understand or modify its operation instead of relying solely on proprietary firmware. By publishing the C-based firmware for the ASM2464PD controller, Comma.ai provides developers with access to the firmware for USB4, Thunderbolt and PCIe-connected hardware.

Ezurio introduces secure software for system modules

Ezurio has introduced EZ BSP, a board support package designed to provide a common software foundation across its system-on-module (SOM) platforms. The software layer sits between silicon-vendor board support packages and the applications, helping developers build and maintain production systems.

EZ BSP emphasises security and reproducibility in software development. It provides capabilities such as reproducible Yocto builds, Hardware Root of Trust provisioning, verified boot, and integrity checks for over-the-air updates. Ezurio also offers a five-year binary guarantee for its software, supporting extended product lifecycles.

The software foundation is designed to support SOM platforms based on processors from companies such as NXP, Texas Instruments, and MediaTek. Ezurio's SOM portfolio combines EZ BSP with security features including secure enclaves, secure boot, signed images, and encrypted certificate provisioning.
