

ForecastHub architecture

Forecast evaluation: Current models and open benchmarking

Using WHO and ICMR outbreak classification guidelines, districts are categorised into low, medium, high and very high-risk zones based on historical disease trends and current case growth.

The dashboards are customised for different users. District health officials receive operational alerts, while state authorities and epidemiologists access broader regional trends for resource planning.

The platform also generates hotspot maps that become particularly

useful after outbreaks begin, helping local authorities prioritise fogging operations, establish fever clinics, and organise community awareness campaigns.

To improve surveillance, ART PARK has developed a larval survey application that allows health workers to report mosquito breeding sites and source reduction activities directly from the field. This information is fed back into forecasting models, continuously improving prediction accuracy.

A plug-and-play AI pipeline

One of the key design goals is to simplify deployment.

The complete forecasting workflow—from data ingestion and preprocessing to model execution and dashboard generation—is packaged into reusable Python modules running inside Docker containers.
