

ChatGPT can now record meetings and read Google Drive

With the latest update, ChatGPT is getting connectors to platforms like Google Drive, Dropbox, Box, OneDrive and SharePoint. This means it can search through your documents, presentations and other files across these platforms to help answer your work-related questions. These integrations will respect the access controls set by your organisation, so ChatGPT only sees what it's allowed to. <https://tinyurl.com/4w7hys3n>

Hackers successfully attacked an AI agent from Microsoft

It didn't start with a ransom note, there were no system crashes, no screens held hostage. Just an AI assistant, Microsoft Copilot, doing exactly what it was designed to do: be helpful. And that's exactly what made it so terrifying. In May 2025, Microsoft quietly patched a critical vulnerability in Copilot, its flagship AI tool embedded across Windows, Office, Teams, and more. Labeled CVE-2025-32711, the fix addressed an issue that, in Microsoft's words, had not been exploited in the wild. Customers were "not affected." <https://tinyurl.com/bdzftv8>

Gentle Singularity: Sam Altman's vision for future of AI

Sam Altman envisions an AI future of transformation and self-building

—By **Vyom Ramani**

When we talk about the future of artificial intelligence, the imagery usually veers towards either a blindingly bright utopia or a stormy dystopian horizon. But Sam Altman, the CEO of OpenAI, offers a vision that's somehow more grounded and more fantastical at the same time, a "gentle singularity" that's both incremental and revolutionary.

His latest blog post outlines a future where intelligence becomes as abundant as energy, and where the changes sneak up on us, bit by bit.

AI's future won't be about a singular moment

Altman dismisses the idea of a sudden AI "takeover" or a single event. Instead, he describes a future unfolding like a gradual, gentle singularity. "The singularity happens bit by bit," he writes, with small wonders becoming routine,

and each new breakthrough laying the groundwork for the next. It's already here in some ways: code-writing agents, AI medical diagnoses, tools that amplify human creativity.

In some ways, this Sam Altman's vision is less about machines seizing control and more about a quiet transformation: "A lot more people will be able to create software, and art," he

writes in his blog, but at the same time, the world will want more of both, and at a faster pace. Experts will still have a role if they're willing to embrace the new tools. The bigger picture is a future where everyone's baseline capability goes up, and expectations rise to meet it.

AI, building AI and the world

One of the most striking ideas Altman explores is the recursive self-improvement loop, not in the sci-fi sense of runaway superintelligence, but in the real-world sense of robots and datacenters that can build each other. He points to a future where humanoid robots aren't just helpers but full participants in the supply chain: mining, refining, manufacturing. And datacenters, the brains of AI, could eventually become self-replicating, driven by the same loops of exponential growth.

This isn't just an abstract concept. Altman believes that once we reach the point where "datacenter production gets automated," the cost of intelligence will collapse to nearly the cost of electricity. He even shares a neat stat: one ChatGPT query today uses about 0.34 watt-hours, just a second or two of your oven's time. If intelligence becomes as cheap as flipping a light switch, the downstream effects on the economy and daily life will be profound. <https://tinyurl.com/4h7rnanv>
