

Xiaomi QLED TV G32

A television that dares to stand out

₹13,999

The Xiaomi QLED TV G32 is a budget offering that brings quantum dot technology to the 32-inch segment, and at 13,999, it's easily one of the most affordable QLED TVs in the market right now. But just how good is the panel? What kind of performance can you expect at this price point? And is this a serious upgrade over typical LED TVs in the budget space? Let's find out.

HOW'S THE DISPLAY LIKE

For this 32-inch QLED, Xiaomi is using a QLED panel, which is a VA LCD panel with a quantum dot layer, and while the resolution tops out at 1366×768 pixels, Xiaomi's tuning combined with QLED tech puts it ahead of most entry-level LED TVs in this bracket.

We used Calman Ultimate with a SpectraCal C6 HDR2000 colourimeter and VideoForge Pro pattern generator to evaluate picture accuracy and colour performance of Xiaomi's QLED TV G32.

In standard mode, brightness peaks at around 200 nits, while vivid mode pushes it to about 304 nits. In movie mode, brightness drops to a more restrained 180 nits.

For contrast, we measured a native contrast ratio of 6082:1, which is excellent for a VA panel in this price segment. This high contrast gives the TV a solid edge in darker scenes where blacks are deep, and shadow details come through well, especially in HDR content.

We recorded 96.3% sRGB and 84.8% of the DCI-P3 gamut coverage, which is actually very respectable for a sub-Rs 15,000 television. Xiaomi's marketing claims around DCI-P3 alignment hold up to a large extent. However, colour accuracy out of the box isn't flawless. The

average DeltaE was 3.9, which is slightly above the ideal range, and the maximum DeltaE hit 8.2 at the 100% red patch, meaning reds are visibly oversaturated.

This explains the noticeable red push in skin tones and some content. Colour smearing and posterisation artefacts also popped up in lower bitrate SDR content, particularly during transitions or in dark gradients. SDR content looks fairly decent in colour-rich scenes, but skin tones in dark HDR content look a bit unnatural.

Now, HDR performance on this TV is mixed. Dark HDR scenes actually render better than expected, and luminance mapping and black levels are handled well.

But in mixed APL scenes, where bright and dark areas coexist, the TV struggles to balance highlights and shadows correctly. You'll notice this especially in dramatic content with lots of light variation. That said, it's typical behaviour for panels in this segment.

Viewing angles are limited, as expected from a basic VA panel. You lose brightness and colour when viewed off-axis, so ensure that you're seated in the centre when viewing the TV.

Motion handling, surprisingly, is better than expected. Slow pan shots and motion scenes play smoothly, without the kind of judder or jitter we've seen on some other budget TVs in this category. There's no MEMC here, but frame rendering is surprisingly stable for a 60Hz panel.
