

Ashwani: 2.5KV surge protection, overcurrent protection, short circuit protection – the works. It's not just talk. Three units have been running at full load in a 40dB ambient for six months straight. Zero failures so far, claims Rajan.

Beyond all its tech specs, it's genuinely one of the smallest GaN chargers I've seen that also charges a laptop, which doesn't feel like a heavy brick in your backpack while on the go. It's super sleek, thoughtfully designed with blinking LED lights that intelligently portray the charging process by the rate at which they blink. As soon as you plug in a device for charging, the Cuzor Pulse's LED indicator lights up and throbs (fade in, fade out) to indicate how fast the device is charging. And once the device is almost 100% charged, the throb effect stabilizes to a more steady, uninterrupted glow.

"As soon as you look at the charger, you'll be able to understand that it's almost like 99% done and you can plug it off, and this is another feature we introduced because we had the freedom to design and didn't want users to constantly keep swiping up their phone screen to see the charging level," Ashwani explained. And this feature works as advertised, well enough to give people who suffer from charge anxiety to stop fidgety movements and relax.

I tested the Cuzor Pulse across a variety of devices – iPhones, power banks, laptops – and the results were encouragingly consistent.

- **iPhone 15 Pro (C1 port):** Went from 8% to 80% in 52 minutes. Power draw fluctuated dynamically, peaking at 18W and intelligently tapering off – just as it should.
- **iPhone 15 Pro (C2 port):** From 1% to 80% in just 50 minutes, hitting a peak of 24W. Slightly faster, suggesting flexibility across both ports.
- **StuffCool Odin Qi2 Wireless Powerbank:** A steady 19.2W draw charged it from 0% to 97% in exactly 2 hours. Linear and dependable.
- **HP OmniBook X Flip 14:** Charged from 5% to 95% in two hours via the smartphone charging port (C1). Impressive crossover capability.

- **Lenovo ThinkPad (C2 port):** From 52% to 97% in 55 minutes. A solid 45% charge added in under an hour with consistent ~40W output.

If you're looking for real-world proof of engineering finesse, both ports of the Cuzor Pulse adapt intelligently depending on the load, heat, and power demand – with stable voltage delivery. Even when running at full 70W load, the voltage drop is negligible, outperforming even Apple in some edge cases.

There's something refreshing about a product that proudly wears its "Made in India" tag without excuses. Cuzor Labs isn't an ODM importer or a rebrander – they're building units from scratch, with custom designs and tight control over every component and thermal spec.

For instance, they're using Navitas GaNSense IC for industry-class performance. "Navitas is one of the pioneers in GaN charging tech. Just like we use Qual-

comm in phones, Navitas is a similar company for GaN," according to Ashwani Rajan. In a world of cookie-cutter chargers, the Pulse stands out for its purpose-built identity. It's a homegrown piece of tech that's globally competent – and in some ways, even globally ahead.

Cuzor Pulse 70W GaN isn't trying to be the smallest or the cheapest charger on the market – I truly think it's trying to be the most thoughtful, not just in its design but also under the hood where it matters the most. And for the most part, it succeeds in that endeavour. Whether you're a MacBook-toting nomad or a minimalist backpacker looking to cut charger clutter, this compact powerhouse (selling for ₹2,499 on Amazon.in) makes a strong case for itself. It's fast, smart, and built to last – with a clean design, clever LED language, and engineering that clearly had humans in mind. And really, what more do you want from a charger? **d**
