

ANC VS ENC

Difference explained for all you non-audiophiles

Vasan GS | editor@digit.in

Noise cancellation is a very quality-of-life feature that can help cut down noise in your daily life. The earphones or headphones can restrict outside noises by simply covering the ear, which is called passive isolation. But modern earphones go further with advanced noise-cancelling technologies that include smart use of microphones and algorithms.

The most popular solution is Active Noise Cancellation (ANC), which, as the name suggests, actively cancels the

ambient noise, and there is also Environmental Noise Cancellation (ENC), which cleans up your sound that goes out to others during calls. While that is the core difference, this article will take a closer look at how ANC and ENC work, the ANC types, which users benefit most from each, and why understanding both technologies matters.

ANC: What is it and how does it work

Active Noise Cancellation works by generating 180° inverse frequen-

cies of the noise to cancel it. So, an ANC headphone collects background outside noises with the mics
