

India as the world's AI developer hub

That's what Github's **Karan MV** truly believes

Jayesh Shinde | editor@digit.in

In a wide-ranging conversation with Karan MV, Director, International Developer Relations at GitHub, I tried to understand what the company is seeing across its global developer ecosystem, especially when AI becomes foundational to how software is built. Karan confirmed several key trends related to AI as a baseline expectation, agents as collaborators, open source as a force multiplier.

In all of this, India is an increasingly central pillar of global software innovation as we move toward 2026 and beyond, suggests GitHub.

AI in coding is now a baseline expectation

At a global level, the sophistication of AI tools at developers' disposal isn't the most striking observation from GitHub. It's how quickly developers have stopped treating them as optional.

"On a yearly basis, we publish what we call the Octoverse report... and what we are seeing is that there are more and more developers who are embracing AI today, a whole lot more than ever before," Karan says.

One data point captures that transition with startling clarity. "Almost 80% of new developers use Copilot within the first week itself, showing that it's almost like a baseline expectation that many developers have."

That statistic matters because it reframes AI adoption entirely. New developers aren't "trying" AI. They assume it's there, the same way they assume version control exists or syntax highlighting works. What began back

in 2021 as intelligent autocomplete has now expanded across the entire software lifecycle.

Karan says, "From just an autocomplete to today where AI and Copilot is a part of every part of the lifecycle – whether you're thinking about writing code, reviewing code, securing code, etc."

This isn't confined to a particular slice of the industry either. "This is happening across open source, across enterprises, across students, academia
