Arm's role in robotics computing

Vyom Ramani | editor@digit.in

If Generative AI defined the last two years of technology, Physical AI is undoubtedly the defining theme of CES 2026. The concept is simple but profound: AI is moving beyond the screen. It is no longer just generating text or images in the cloud; it is now perceiving, reasoning, and acting in the real world. As NVIDIA CEO Jensen Huang declared at the event, the "ChatGPT moment for physical AI is here."

The constraints of the real world

Bringing intelligence into the physical world presents a unique set of engineering challenges that cloud-based models simply do not face. A robot or an autonomous

vehicle cannot afford the latency of sending data back and forth to a data center. If a humanoid robot slips, it needs to correct its balance in milliseconds,

not seconds. Furthermore, these machines operate on battery power, meaning they cannot rely on the energy-hungry cooling systems of server farms.

The shift to Physical AI is fundamentally a shift from centralized cloud computing to decentralized edge computing. In the data center, raw power is king. In the real world, efficiency is the new performance. This is why the major robotics announcements at CES 2026 all share a common DNA: they are built on Arm.

Silicon for the new machine age

NVIDIA's flagship platform for humanoid robots, Jetson Thor, serves as a prime example of this architectural dominance. Designed to function as the brain inside a robot's torso, it delivers massive AI performance to run complex multimodal models locally. At the heart of this system lies the Arm Neoverse V3AE CPU. The "AE" stands for Automotive Enhanced, bringing server-class performance to the edge while integrating critical safety features required for machines that operate near humans.

We are currently witnessing the untethering of AI like we have never seen before. tinyurl.com/yc22a8uc

PHYSICAL AI PRODUCTS

CERAGEM Youth Bed with AI Health Concierge

Beds are becoming health platforms, and CERAGEM's Youth Bed is among the most advanced. Sensors track posture, sleep quality, and physiological signals while an AI concierge offers personalised recommendations. Unlike typical sleep trackers, this system actively adapts the bed itself, adjusting support and temperature.

John Deere Autonomy Kit (NVIDIA Orin platform system)

This upgraded autonomy package transforms tractors into intelligent, roving sensor hubs, featuring 16-camera perception arrays and NVIDIA Orin processors, it processes visual data locally to minimize latency for high-speed autonomous tillage. The system also analyzes real-time soil and nutrient levels for better intelligence.

Boston Dynamics Atlas (Electric)

RIP, hydraulics. The fully electric Atlas, showcased at the Hyundai booth, is leaner, quieter, and somehow even more unnerving than its predecessor. While it lacks the "human" constraints of joint limits - witness the "Exorcist-style" head and torso spins - that's exactly the point. It doesn't need to move like a human to work.

LG CLOiD

The CLOiD isn't a bipedal walker (it rolls on a stable wheeled base), but it has a humanoid torso and two 7-degree-of-freedom arms with five-fingered hands and it actually integrates. Using LG's ThinQ ecosystem, the CLOiD was shown opening a smart fridge, retrieving ingredients, and setting an oven. It's not trying to just simulate a human, but be so much more.
