

```
Usage: cursor-agent [options] [command]

Cursor Agent

Options:
  -v, --version            Output the version number
  -a, --api-key <key>     API key for authentication (can also use CURSOR_API_KEY)
  -p, --print              Print responses to console (for non-interactive use).
                          write and hash. (default: false)
  --output-format <format> Output format (only works with --print)
  --fullscreen            Enable fullscreen mode (default: false)
  --resume [chatId]       Resume a chat session. (default: false)
  -m, --model <model>     Model to use (e.g., gpt-5, sonnet-4, sonnet-4-thinking)
  -f, --force             Force allow commands unless explicitly denied

Commands:
  login                   Authenticate with Cursor
  logout                 Sign out and clear stored authentication
  status                 Check authentication status
  ls                     Resume a chat session
  resume                 Resume the latest chat session

> Plan, search, build anything
```

code with AI is that it felt like the editor knew what I was trying to build and not just what I was typing.

How to code using Cursor

Using Cursor for coding is easy; all you need to do is follow the steps below:

1. Install Cursor and open your existing project, not a demo folder.
2. Let it index your full codebase so it learns structure and patterns.
3. Use inline prompts to ask for changes directly inside files.
4. Highlight code and ask for refactors, fixes, or explanations.
5. Use chat to ask project-level questions like how parts connect.
6. Accept or reject suggestions line by line to stay in control.

My friends and I often joke that Cursor reads the room of our codebase. Aside from that, it also understands relationships between files, catches patterns we forgot existed, and suggests changes that actually fit our project instead of generic fixes.

Codex

If you find Claude and Cursor exciting, you should try Codex. The tool from ChatGPT is built differently. Much like other tools in the list, it does not want to talk much, but rather it wants to build what it's asked to. Handing tasks to Codex feels like assigning work to a fast junior developer who never complains. It can generate large chunks of code, handle repetitive changes, and execute clear instructions at scale.

How to code using Codex

If you want to use Codex, then you need to have an active ChatGPT premium subscription. If you have one, then you can follow the steps below:

1. Head to ChatGPT, and in the menu on the right, find Codex and press it.
2. Define what you want to build, including the programming language, goal and constraints.

3. Describe the task in plain English. You can also provide context or existing code.
4. Generate full functions or modules.
5. Review outputs before merging.
6. Use it for repetitive or large-scale changes, if any.
7. Use tests to validate results.

Codex is most useful when the workload is heavy, even if the work isn't creative. It saves time and energy as long as you review its output. When used wisely,

Codex can turn long coding sessions into shorter, more focused ones.

How developers combine Cursor, Claude, and Codex

While each of the above-mentioned tools is capable of handling coding requests on its own, most developers do not rely on a single tool alone. After speaking with various coders in the industry, I learnt that developers don't pick one tool and ignore the rest; instead, they use them together in a complementary way. Typically, developers start with Claude to shape and refine ideas, then use Cursor to assist with writing code, and finally turn to Codex for large-scale bug fixing or comprehensive code review.

One developer told me, 'I talk to Claude before I open my editor. It helps me clear my head.' Once the plan feels right, you move into Cursor. You write code with AI suggestions flowing inline,

adjusting and refining as you go. When a task grows boring, Codex steps in.

Another developer said, 'Codex handles the heavy lifting, Cursor keeps me grounded, and Claude keeps me sane.' These tools work best on different mental states. Thinking, writing, and executing: they cooperate. ➡
