

This guy saved his dog from cancer by using ChatGPT

When chemotherapy failed his rescue dog Rosie, Sydney data engineer Paul Conyngham used ChatGPT to do something extraordinary. With no biology background, he ran genomic sequencing, mapped tumour mutations using DeepMind's AlphaFold, identified drug targets, and ultimately helped UNSW researchers build a personalised mRNA cancer vaccine, the first ever designed for a dog. tinyurl.com/7x9lie8r

OpenAI plans superapp to merge ChatGPT, Codex & Atlas browser

OpenAI is building a desktop superapp that combines ChatGPT, its Codex coding platform, and the Atlas browser into one unified product. Chief of Applications Fidji Simo will lead the project, with the focus on agentic AI features that let the system perform tasks autonomously. The move is driven by internal fragmentation concerns and intensifying competition, particularly from Anthropic. The mobile app stays unchanged for now. tinyurl.com/o21a85

NVIDIA's GTC 2026 vision

Jensen Huang's AI future goes beyond just chat

—By **Jayesh Shinde**

Every year, GTC keynotes are judged by NVIDIA's hardware flex. More CUDA, more cores, more things named after scientists who never imagined becoming GPU roadmaps. But at GTC 2026, Jensen Huang's real message wasn't about silicon alone, as is his usual wont. It was about where AI is going next, and why NVIDIA believes it's building the industrial plumbing for that future.

Huang laid out AI's evolution like a staircase. Perception led to generation, generation led to reasoning, and reasoning is now leading to something more consequential, systems that don't just answer, but execute. "For the first time, you don't ask AI what, where, when, how. You ask it to create, do, build." If generative AI was the era of amazement, agentic AI is supposed to be the era of labour. Digital labour, where humans supervise systems and machines rather than operate them directly, believes NVIDIA's Jensen Huang.

The data problem nobody talks about

Huang's most revealing lines had

nothing to do with chips. "Structured data is the foundation of trustworthy AI," he argued, pushing back against the idea that enterprises will simply hand their operations to a chatbot. Businesses run on records, workflows, and governance rules. AI that wants

to operate inside them has to plug in without hallucinating its way into a compliance disaster.

He went further, pointing to the vast swamp of data businesses generate but barely use. Around 90% of data created annually is unstructured. PDFs, documents, media, historically useless for computation. Huang's vision is making that data queryable, turning passive information into something AI can reason

over. Not merely generating answers, but making passive data computable.

The token factory

"Finally, AI is able to do productive work, and therefore, the inflection point of inference has arrived." If training built

the AI boom, Huang believes inference will define its economics going forward. That shift reframes what a data centre actually is. "Your data centre used to be a data centre for files. It's now a factory to generate tokens." The phrase token factory may be the one that defines NVIDIA's next

decade — not a cloud, not a server room, but a production system measured in cost per token and usefulness per watt.

NVIDIA still sells the chips, accelerators, and server racks. But Huang's bigger claim is that AI is becoming infrastructure. Computing used to be about retrieval. Now it's about generation, reasoning, and action — and NVIDIA wants to be the factory behind the factories.
