

5 key Codex features

You must try in GPT 5.4

Bhaskar Sharma | editor@digit.in

A I has been a coding buddy for programmers for quite some time now, whether it's helping spot errors, fix bugs, or even with something as fundamental as building logic. Furthermore, Codex from OpenAI has become one of the most loved AI tools in the developer community, not just because of the solutions it provides but also because of the way it explains and teaches concepts.

What's even more impressive is how consistently OpenAI has been improving its GPT models to make them more friendly for developers. Some time ago, they launched Codex, and since then the company has continued to expand its capabilities. Recently, they also introduced a dedicated Codex app that focuses on helping developers

manage larger coding tasks with more automation and better structure.

After spending some time testing the latest GPT5.4 model in the Codes app with small projects and experiments, I discovered a few features that are definitely worth trying. So without any further ado, let's deep dive into the must-try Codex features in GPT5.4.

01 Autonomous AI coding agents

One of the very first Codex features I tested was the idea of autonomous coding agents. Instead of asking Codex for small pieces of code, I tried giving it a full task to see how it would respond. I asked Codex to create a simple Python task manager using Flask. Normally the AI generates a small

code snippet and stops there. However, with the latest Codex models, it actually started suggesting a project structure.

It suggested a folder layout, created routes for adding and completing tasks, and even wrote a basic HTML template. I was surprised because the response felt like someone had thought through the whole feature before writing code.

After that I kept modifying the project to my liking. I asked Codex to add login functionality and basic error handling. What surprised me was that, unlike the old times, it adjusted the earlier code and explained the changes instead of replacing everything and writing everything again from scratch.

From my experience, this feature works best when you give a clear goal. Rather than asking for one function at a time, you describe the feature you want to build. Codex breaks the work into smaller steps and starts generating code that fits the overall structure.

However, it still requires human supervision, but it removes a lot of time consuming setup work.

02 Multiple tasks in a single workflow

One major limitation of earlier AI assistants was that they could only do one task at a time. With the Codex experience, the system can work on several development tasks in the same workflow. This makes handling different parts of a project easier.

I gave Codex two tasks in a single prompt to evaluate the feature. First I asked it to debug a Python script that was using too much memory, while also asking it to create a small React interface to display the script's output.

Codex treated the tasks as separate problems and started analysing the Python code while also generating the React components. The response suggested that the tasks were being handled independently in the same request.

For someone who often experiments with both backend and frontend ideas,
