

Redmi Note 15 Pro+

Makes more sense the longer you own it

For a decade, the Redmi Note was the easiest phone recommendation in India.

You didn't need to think too hard about it because you got good specs at aggressive price. But in 2026, Xiaomi seems less interested in winning spec-sheet arguments and more focused on building a phone people will use for years. The Redmi Note 15 Pro+ is the clearest expression of that manifesto. It's got a bigger battery, better durability, longer software support and a simple camera system. Starting at Rs 37,999, here's why it should be on your radar.

DESIGN AND BUILD

The Redmi Note 15 Pro+ is a big phone. The 6.83-inch display makes it tall and wide and there's no getting around that. But despite packing a larger screen and a substantially bigger battery than last year's Note 14 Pro+, it's actually slimmer at 8.1mm compared to 8.8mm. That's a noticeable difference when you hold both back to back. It doesn't feel bulky or top-heavy, which is impressive given the 6,500mAh battery inside.

The quad-curved front gives it a more premium visual identity than any Redmi Note before it. The back panel is clean and modern and depending on the colour variant you choose, there is a matte finish design with Mirage Blue and Carbon Black and a textured back design with the Coffee Mocha model. This phone looks like it belongs at a higher price than it actually commands.

Durability is where Xiaomi has pushed hardest this generation. You get IP66, IP68, IP69 and IP69K ratings. In addition, there's Gorilla Glass Victus 2 up front and improved internal

₹37,999

reinforcement. This is a phone that's been designed with the understanding that people drop things, spill things and don't always treat their devices like museum pieces. If you're someone who keeps a phone for three or four years, this kind of build quality compounds in value over time in ways that a faster processor or an extra camera lens simply doesn't.

DISPLAY

The 6.83-inch AMOLED panel runs at 1.5K resolution with 120Hz refresh, HDR10+, Dolby Vision and 3840Hz PWM dimming. In testing, peak brightness hit around 2,800 nits in auto mode, which makes outdoor readability comfortable even under harsh sunlight. Contrast is, as expected from OLED, essentially infinite. The blacks are pitch perfect and the panel's gamma tracks at 2.24, almost dead on the 2.2 target.

Shadows render smoothly without looking crushed or artificially lifted.

Colour gamut coverage sits at 99.1%, so content looks vivid and saturated. This is a display that makes movies, photos and even everyday UI elements feel alive. Pair that with the Dolby

Atmos stereo speakers and you've got a largely enjoyable media consumption experience for the price.

The default colour temperature runs at 7,432K, which is meaningfully cooler than the 6,500K standard.

You'll notice a blue tint in whites, greys and lighter UI elements. The average colour DeltaE is at 2.9,

which is within the "good enough for most people" range, but the max error spikes to 7.2 at the white point, again correlating with that cool tint pulling lighter colours off target.

The fix is to switch to Original Colour Pro or a warmer colour profile in settings that reins in the blue cast significantly. But it's worth knowing that the out-of-the-box experience leans noticeably cool and if you care about accuracy, you'll want to spend a minute in display settings before you start using the phone in earnest.

CAMERA

This is where Xiaomi has made its most controversial decision. Where the Note 14 Pro+ gave you a 50MP main, 50MP telephoto and 50MP ultrawide, the Note 15 Pro+ ditches the telephoto and simplifies to a 200MP Samsung HPE main sensor paired with an 8MP ultrawide. Zoom duties are handled entirely through in-sensor crop. If you relied on optical zoom for portraits, street photography or any scenario where you need to reach into a scene, this is a real loss for those who used it.

Xiaomi's argument (and you can read more about it here) is that the 200MP sensor with advanced pixel binning and multi-focal processing can compensate and most people were not using the telephoto lens anyway. Daylight performance is strong, where
