

We use it to test the relative performance of the iGPU to discrete GPUs and where iGPUs stand amongst others. With both companies improving their integrated graphics stack, it allows us to measure how well the iGPU performs and if it can handle eSports titles.

THERMALS AND POWER

The Core Ultra 7 270K Plus behaved better than its power envelope might suggest. In this setup, CPU package temperature averaged 57°C and peaked at 80°C, which is a tidy result for a desktop chip rated to turbo up to 250W.

Power figures were more revealing. Average package power came in at 230W, with a peak of 250W, effectively brushing right up against Intel's official turbo ceiling. The 270K Plus is willing to spend power to hold performance, and it expects the rest of the platform to keep up. The upside is that thermals remain manageable with a competent 360 mm liquid cooler. The downside is obvious too: this is not a chip for bargain cooling or casual airflow planning. It runs under control, but it absolutely likes to eat. Intel officially rates the part at 125 W base and 250 W maximum turbo power, and these readings line up very closely with that behaviour.

VERDICT

The Intel Core Ultra 7 270K Plus lands as a much more convincing desktop Core Ultra processor than the 265K ever was. It looks stronger on paper, feels better balanced in the current desktop market, and brings the sort of multi-threaded weight and platform features that make sense in a premium mainstream build. It fixes several of the earlier chip's weak spots, especially in productivity and in gaming uplift versus the original Arrow Lake desktop parts, though AMD's X3D lineup still keeps a grip on the outright gaming crown in a fair number of titles. That said, this test unit's thermal and power behaviour shows that Intel has achieved its gains by letting the chip run hard and demanding proper cooling.
