

Invisible rays

The light we see makes up a tiny part of the energy that comes from the Sun. Beams of visible light and invisible rays make up something called the electromagnetic spectrum. Both are made of particles, called photons, and travel in waves. The photons of different rays have different amounts of energy. We can only detect these rays using special instruments.

! WOW!

Some **snakes** can **see infrared**. It helps them to find **warm prey**.

Gamma rays

Gamma rays have photons with the most energy. They are dangerous rays that are made by nuclear explosions and radioactive materials. They also come from exploding stars! This picture shows gamma rays from space in orange.

Radio waves

Radio waves are used to carry signals. We use them to transmit television and radio programmes, which are picked up by appliances that change the signals into sound and pictures.
