

Sound waves spread out as they travel further from their source.

As the energy of the waves is spread over a larger area they sound quieter.

Echoes

Echoes happen when a sound wave bounces off something and comes back. Echoes don't take long to return, as sound travels quickly.

Rocky surfaces reflect sound well, producing clear echoes.

Pitch

The faster something vibrates, the higher the sound it makes. Slower vibrations make lower sounds. Pitch is the word we use to describe how high or low a sound is.

Covering different holes on a recorder changes the pitch of the sound.

Volume

The bigger the vibration of something, the more energy it has and the louder the volume of the sound produced. Smaller vibrations make quieter sounds.
