

LG OLED G6

One of the most complete TVs I have tested this year

₹2,33,990

Last year, when we tested the LG OLED G5, we

found it to be one of the best OLED TVs for a mainstream audience. And even though it didn't offer the most authentic colours, everyone, except us testers, seemed to prefer LG's visual treatment over the competition. It was another interesting example of the difference between critics' and the public's reactions to creative work. So, when the LG OLED G6 reached the Digit Test Labs, I decided to look beyond the critical lens when needed and see how much better the new LG TV really is, and whether it has improved enough to be a clear winner for both the critic and the user in me.

In this LG OLED G6 TV review, I will be testing its upgraded reflection handling, colour accuracy with the new Hyper Radiant Color Tech, brightness and black levels from the Primary RGB Tandem OLED panel, sound from the new speaker setup, the experience of webOS 26, and more.

In India, the 65-inch LG OLED G6 is currently available for Rs 2.3 lakh. The question, therefore, is not whether the G6 produces a good picture. It does. The more important question is whether its improvements are visible enough to justify spending this much. After spending time with it across movies, television, sports, and games, the answer is mostly yes.

BRIGHT WITH TRUE BLACKS

The biggest change with the G6 TV is brightness. LG's new OLED panel is said to have up to 3.9 times higher peak brightness than conventional OLED in a 3% window with its Brightness Booster Ultra system.

Our Calman Ultimate measurements show just how far the G6 can go with small HDR highlights. At a 1% window, the panel reached around 2,970 nits. It stayed close to that level at 2% and 5% windows. At 10%, brightness was still around 2,850 nits. The drop becomes more noticeable as more of

the screen turns white. We measured roughly 1,300 nits at 25%, around 680 nits at 50%, approximately 510 nits at 75%, and 435.6 nits with a full 100% white window.

The higher peak brightness makes an impact in headlights, sparks, reflections, sunlight, or explosions against a darker background. One of my favourite scenes for testing this is the underwater sequence in Mission: Impossible – The Final Reckoning, where Tom Cruise's character dives to the wreck of a sunken submarine. The scene moves between the almost pitch-black depths of the ocean, the dimly lit interior of the submarine, and sudden bursts of light from his gear and the vessel's internal lights. At the same time, 435.6 nits across a full-screen white pattern is a useful result for everyday viewing. It means large, bright scenes, such as a cricket pitch, a snowy landscape, or a bright daytime exterior, do not look as restrained as they can on older OLEDs.

On the other hand, the LG OLED G6 registered 0 cd/m² on a black pattern. This means the TV can produce the deep blacks and extremely high contrast that you buy an OLED for. It was a visual treat to watch dark, nightly, HDR sequences in movies and shows. You see this in The Revenant, where Leonardo DiCaprio's character emerges from the darkness as a group of horse riders approaches, carrying fire lamps. Most of the frame is extremely dark, while the lamps create small, intense pools of light. There was no blooming or unnecessary lifting of blacks.

But I did notice some banding in the underwater sequence in Mission Impossible: Final Reckoning, when Tom Cruise's character settles on the oceanbed. So, you realise even the best is not flawless when you look closely.

In the Calman tests, we saw the G6 isn't perfectly aligned with the reference across the entire greyscale range. We got an average Delta E of 3 with some luminance error in the Greyscale Multipoint test. But the Colorchecker analysis was more encouraging with a Delta E of 1.84.
