

other words, if you only check one place and assume the rest is taken care of, you are already gambling.

There is also the storage question. Google's India-facing Google One page currently lists 30GB, 100GB, and 2TB consumer storage tiers, and it explicitly describes that storage as space for photos, files, and device backups. That matters because your Android backup does not live in some magical parallel universe. If your Google storage is clogged with Gmail attachments, Drive clutter, and years of Photos uploads, your backup strategy can quietly choke without announcing a dramatic funeral.

So let us build an Android backup system the way normal people should: in layers.

Step 1: Check which Google account is being backed up

On many Android phones, people are signed into more than one Google account. One is for Gmail, one is for YouTube, one is an old college account, one is the account they accidentally created while setting up a phone at 1 a.m. Google Photos lets you choose which account receives your photo and video backups, and Google's own instructions tell you to go into Google Photos > Profile picture > Photos settings > Backup, then check the backup account under "Account & Storage." The Photos help pages also specifically say you can switch to a different account for backup from that menu.

Why does this matter? Because if your photos are backing up to one Google account while device data is tied to another, restoring a phone later can become needlessly chaotic.

Step 2: Turn on Android device backup properly

Now go to the system-level backup settings. Google's official Android support page says the path is Settings > Google services > All services > Backup. There, you can turn backup on or off and choose whether to include Photos & videos, Device data, or both. Google also says backups can take up to 24 hours to complete,

which is important because users often expect instant reassurance and then assume nothing is happening if the status does not change immediately.

Do this now:

1. Open Settings on your Android phone.
2. Tap Google services.
3. Tap All services.
4. Find Backup.
5. Turn on backup for Device data and, where relevant, Photos & videos.
6. Leave the phone on Wi-Fi and power for a while so the first full backup can complete.

This layer matters because system backup is what helps with restoration when you move to a new Android phone or recover after a reset. Google's Android migration help also explains that when setting up a new Android device, you can copy apps and data from the old phone through guided setup flows.

Step 3: Turn on Google Photos backup, then tame it

Photos are where Android backup either becomes magical or monstrous.

Google Photos' Android help pages show the route clearly: open Google Photos, tap your profile picture, go to Photos settings, then Backup. From there, you can turn backup on, review the account being used, and change other controls. Google also provides a dedicated page to check your backup, which advises confirming that backup is on and that the correct Google account is selected.

Do this now:

1. Open Google Photos.
2. Tap your profile picture.
3. Tap Photos settings.
4. Tap Backup.
