

PMs, Email and Safer Contacts

Communicate privately without exposing more than the message

A message can be unreadable to outsiders and still reveal who spoke, when they spoke, how often they communicate and which devices were involved. That distinction matters because communication privacy has two layers. The first is content: the words, photographs, files and calls themselves. The second is metadata: sender, recipient, time, duration, account identifier, network address and contact relationships.

End-to-end encryption is designed so that message content can be read only on the participants' devices rather than by every

server carrying it. It is valuable, but it does not prevent a recipient from copying the message, photographing the screen or showing it to someone else. It also cannot protect a conversation when either device is unlocked, infected or backed up insecurely.

The goal is not merely to "use an encrypted app". Choose the correct identity, minimise contact details, verify the person and control how long the conversation remains available.

What encryption doesn't hide

Ordinary transport encryption protects data while it travels
