

Security Control	Android	iOS	Windows	macOS
OS Updates & Patching	Settings → Security → Security update → Auto-download	Settings → General → Software Update → Automatic Updates	Settings → Update & Security → Windows Update → Auto-download	System Settings → General → Software Update → Auto-update
Secure Boot Chain	Verify "ro.boot.verifiedbootstate" via ADB; keep OEM Unlocking off	Boot ROM → LLB → iBoot → kernel verification	UEFI Settings → Secure Boot ON; TPM init; enable BitLocker	FileVault ON; Terminal → `csrutil status` (ensure SIP enabled)
Full-Disk Encryption	Settings → Security → Encrypt phone	Enabled automatically when passcode set	Control Panel → BitLocker Drive Encryption → Turn On	System Settings → Privacy & Security → FileVault → Turn On
Disable Unused Services	Settings → Apps & notifications → Disable bloatware; Quick-settings radios OFF	Settings → General → Background App Refresh OFF; Cellular OFF per app; Lock-screen widgets OFF	Control Panel → Programs → Turn Windows features off; Services.msc disable unneeded	System Settings → General → Login Items OFF; Sharing OFF
Firewall & Network Filters	Install AFWall+ or NoRoot Firewall; configure per-app rules	Use Lockdown/ Guardian Firewall; DNS filtering via NextDNS	Windows Defender Firewall → Advanced Settings → Inbound/ Outbound rules	System Settings → Network → Firewall → Options → Block apps
Sandboxing & Containers	Android Enterprise Work Profile or Island app profile	Deploy managed apps via MDM with per-app VPN & DLP	Windows Sandbox; use virtual desktops via Hyper-V or VMware	Run isolated VMs in Parallels, VMware Fusion, or via Virtualization framework

2. Transfer data selectively

- Copy files into the work profile only as needed, preventing cross-profile leaks.

3. Apply additional restrictions

- Within the work profile, disable screen capture, screenshots, or data sharing to the personal side.

iOS Managed apps and data separation

1. Deploy managed apps via MDM

- Corporate apps receive per-app VPN, DLP policies, and selective wipe capabilities without affecting personal apps.

2. Use Apple's Secure Enclave for key storage

- Managed apps can leverage the Secure Enclave to store cryptographic keys outside the main filesystem.

3. Implement per-app passcodes

- In MDM settings, enforce a PIN on each managed app, adding a layer of access control.

Desktop containers and virtualization

1. Windows Sandbox & Virtual Desktops

- Windows 10/11 Pro: Enable Windows Sandbox to test untrusted applications in an isolated environment.

2. macOS Virtualization Framework

- Use VMware Fusion or Parallels to run separate macOS/ Windows instances for testing or risky workflows.

3. Linux VMs & WSL2

- On Windows, install Windows Subsystem for Linux 2 to contain CLI-based tools away from the host system.

Through device hardening and OS-level security, you've built a resilient foundation that drastically reduces common attack vectors. By automating patches, enforcing secure boot chains, disabling extraneous features, tuning firewalls, and strengthening sandbox boundaries, your devices now present a far more formidable challenge to would-be attackers. **[1]**
