

3. Shield against relay

- Use RFID-blocking wallets or sleeves to prevent unauthorized scanning when in your pocket.

4. Audit installed NFC apps

- Remove any unfamiliar NFC-based tools; keep only official payment and ticketing apps.

Example: While commuting, Kavita enables NFC only during tap-in at metro gates, minimizing risk of relay or eavesdropping attacks.

App firewalls and DNS-level filtering

Per-app firewalls let you control which applications can send or receive network traffic, while DNS-level filtering blocks malicious domains before connections are made. Together, they form a powerful layer of defense on the move.

Configuring per-app firewalls on Android

1. Install NoRoot firewall

- Open Google Play Store and install NoRoot firewall.

2. Grant VPN permission

- On first launch, the app will prompt you to allow it to create a local VPN; tap OK to grant this permission.

3. Define rules per app

- In the main rule screen, you'll see two columns: Wi-Fi and Mobile Data. Tap the red cross next to any app to block its network access, or the green check to allow it.

4. Enable logging and alerts

- In Settings → Log, turn on Enable Log to record connection attempts and configure notifications for blocked traffic.

5. Review and update rules regularly

- Periodically revisit the rule list to adjust access – for instance, blocking background-only apps to conserve data and battery.

App blocking on iOS with network extension firewalls

1. Choose a firewall app

- Install Lockdown or Guardian Firewall from the App Store;

these leverage Apple's Network Extension APIs to filter traffic per app.

2. Allow VPN configuration

- On first run, the app will prompt you to add a VPN profile – tap Allow to let it filter network traffic.

3. Create whitelist / blacklist rules

- Within the app's UI, navigate to Apps and toggle each installed app to Block or Allow internet access.

4. Monitor Blocked Connections

- Use the built-in analytics dashboard to see which apps attempted connections and adjust your rules accordingly.

DNS-level filtering for all traffic

CleanBrowsing on iOS

1. Install the CleanBrowsing app or profile

- Download CleanBrowsing from the App Store or install the manual [.mobileconfig](#) profile from [cleanbrowsing.org](#).

2. Select a filter policy

- Choose from Security, Adult, or Family filters to block phishing, malware, and unwanted content at the DNS level.

3. Verify activation

- In Settings → Wi-Fi → DNS, you should see CleanBrowsing's resolver IPs (e.g., [185.228.168.168](#)); test with a blocked domain to confirm.

DNSFilter roaming client on Android and iOS

1. Deploy via MDM or single install

- For enterprise use, push the DNSFilter Roaming Client APK (Android) or app (iOS) via your MDM solution; standalone users can install directly.

2. Authenticate and register device

- Launch the app and sign in with your DNSFilter account; devices will appear in the DNSFilter dashboard under Roaming Devices.

3. Enforce policies

- In the DNSFilter portal, attach the device to a policy (e.g., Security+), which automatically blocks malicious domains, phishing, and adult content.

4. Monitor DNS logs

- Use the dashboard's Queries view to see every DNS lookup and identify repeated attempts to reach blocked sites.
