

Microsoft open sources 'pg_durable' extension

Microsoft has open sourced `pg_durable`, a PostgreSQL extension that lets developers build long-running, fault-tolerant software workflows directly inside the database.

The extension introduces durable execution natively to PostgreSQL, eliminating the need for developers to patch together external tools like background workers, message queues, and external orchestration engines. Workflows are defined using standard SQL, allowing PostgreSQL to automatically track execution progress, handle retries, and recover states following unexpected server crashes or database restarts.

By shifting workflow state tracking directly into PostgreSQL tables, `pg_durable` guarantees that long-running data processes can survive unexpected system failures and automatically pick up from their last recorded checkpoint. The extension provides developers with dedicated SQL operators designed specifically for managing sequential steps and parallel tasks, making it highly optimised for asynchronous tasks.

Architecturally minimal, the open source extension runs via a native Postgres background worker with no external control plane requirements. The underlying orchestration runtime is powered by two new Microsoft-developed Rust libraries: `durooxide`, which coordinates deterministic event tracking, and `durooxide-pg`, which handles state persistence in a dedicated schema.

The `pg_durable` extension is available on GitHub and ships natively as part of Microsoft's Azure HorizonDB cloud service.

removing operational overhead, preserving workload portability and keeping data within customer cloud environments.

The managed service keeps customers on standard upstream Kubeflow while Canonical handles upgrades, security patches, version migrations, backups and operator maintenance. According to the company, the approach reduces the day-two operational burden of running Kubeflow without changing the underlying open source platform, allowing workloads to remain portable across environments.

The platform runs entirely inside a customer's Azure tenancy, meaning data, models and training workloads never leave the organisation's cloud environment. Canonical says this design supports compliance and data sovereignty requirements while giving organisations full control of their infrastructure.

The company positions the service as a solution to common Kubeflow operational challenges, including Istio configuration, Kubernetes API changes, storage provisioning, GPU scheduling and the complexity of integrating multiple open source components such as Katib, Pipelines, Notebooks and Central Dashboard.

CData launches open source tools to help build AI apps faster

CData Software has released three new tools to help developers build artificial intelligence apps faster. The lineup includes a free version of Connect AI, an open source Python tool, and a command-line program. Together, they let programmers safely connect AI models directly to large business platforms like Salesforce, Snowflake, and Microsoft 365.

Usually, tech projects slow down because software engineers must wait weeks for IT departments to grant access to company databases. CData solves this issue by giving IT teams full control and visibility over data security, while allowing developers to pull the information they need instantly.

By offering these tools for free and making the Python code open source, CData hopes to remove the friction between engineering speed and company safety rules.

Tigera launches Lynx to govern Kubernetes-native AI agents

Tigera, the inventor and maintainer of Calico Open Source, has announced the general availability of Lynx, a unified control plane designed to secure and govern Kubernetes-native AI agents.

Lynx is built on open standards rather than proprietary frameworks, integrating with Microsoft Entra ID, Okta, SPIFFE/SPIRE, and OpenTelemetry. Its capabilities span agent discovery and observability, posture management, identity and authentication, policy enforcement, and anomalous behaviour detection. The platform uses eBPF-powered discovery, cryptographic identities, default-deny policies enforced through the Cedar policy language, and kernel-level monitoring via eBPF and Linux Security Modules to detect threats such as credential theft and lateral movement.

"For over a decade, Tigera's Calico platform has served Global 2000 companies running the largest Kubernetes platforms in the world, securing tens of millions of mission-critical transactions every day. AI agents are the next class of workloads: autonomous, distributed, and increasingly embedded in critical business processes. Lynx brings that same unified control and security rigor to AI agents," said Ratan Tipirneni, CEO of Tigera.
