

Figure 4: A decision guide for reaching for each tool. Start with plain open source libraries, move to Scrapy for scale, and add each API capability only against the specific wall you hit

works through the pipeline for you. It explores the site to find listing and detail pages, proposes an extraction schema with sample data so you can sanity-check the fields, generates a Scrapy spider with web-poet page objects along the lines of the ones above, and smoke-tests the result.

Wrapping up

The reason web scraping feels harder than it should is that we tend to treat it as one problem when it is really two. Crawling a site, following its links,

and streaming out records is a solved problem, and Scrapy solves it well without asking you for a cent. Getting past bot defences, rendering JavaScript, and extracting clean structured data across sites that keep changing is the genuinely hard part, and that is the part worth handing to a single API call so you stop maintaining infrastructure and

start using data. Split the work along that line and most scraping projects get dramatically smaller. If you want to go deeper, the Scrapy documentation at docs.scrapy.org is the best place to learn the framework, and the Zyte API reference at docs.zyte.com documents every field mentioned here and many more. **END** 🐧
