

Yale researchers propose licensing framework for generative AI

Researchers at Yale University's Digital Ethics Center (DEC) have proposed a new licensing framework designed to ensure that generative AI models built on open source code remain open and transparent.

Called the Contextual Copyleft AI License (CCAI), the proposal extends traditional open source copyleft principles to generative AI by treating AI models trained on open source code as derivative works. Under the framework, developers using open source software for AI training would be required to publicly disclose their model architecture and training data.

The researchers argue that many AI companies benefit from open source software without providing equivalent transparency in return, leaving developers with little visibility into how their code is used or whether resulting AI systems remain open.

"Our analysis showed that extending the copyleft concept to generative artificial intelligence has the potential to give open source software developers meaningful control over how AI developers use their code," said Grant Shanklin, lead author and de Vries-Sherif junior fellow at DEC.

According to the study, the proposed licence would give developers greater control over AI use of their code, encourage the creation of more fully open source AI models, improve transparency and accountability, and help curb 'open washing' by organisations that market proprietary AI systems as open.

cryptocurrencies such as Bitcoin and Ethereum should not be held liable for how end users utilise their software.

Speaking on CNBC, Lummis said developers typically have no control over or visibility into who ultimately uses their code. "Once they've written the code, they don't know who the end user is," she said.

The Wyoming senator also pushed back against criticism of the legislation from JPMorgan CEO Jamie Dimon, calling his assessment of the bill "absolutely wrong."

A key point of contention is the bill's anti-money laundering (AML) framework. Lummis said the CLARITY Act contains more than 1,600 references to existing AML and Bank Secrecy Act (BSA) requirements and would continue applying those provisions to digital-asset activities.

Dimon has argued that crypto firms performing bank-like functions should be subject to the same AML, know-your-customer (KYC), and regulatory requirements as traditional banks. He has also warned that stablecoin issuers could operate under lighter regulations than banks.

Pluto.jl reaches version 1.0 with a stable API

Pluto.jl, Julia's most-starred open source package, has reached version 1.0, marking its transition to production-ready status and delivering a stable API that researchers, educators and institutions can rely on for long-term deployments.

The milestone is significant because Pluto was built to address reproducibility challenges that have long affected Jupyter notebooks. Studies cited by the project found that only 879 out of 10,388 biomedical Jupyter notebooks reproduced identical results when rerun in clean environments, while an analysis of 1.4 million GitHub-hosted Jupyter notebooks identified hidden state and out-of-order execution as major causes of reproducibility failures.

Pluto tackles the issue through an open source dependency-graph architecture powered by ExpressionExplorer.jl and PlutoDependencyExplorer.jl. The system performs static code analysis, constructs a dependency graph and automatically re-executes affected cells whenever changes occur. Variables are removed from scope when their defining cells are deleted, ensuring notebook state always reflects the visible code. While the 1.0 release itself involved only a small code update, its importance lies in the project's commitment to API stability, long-term compatibility and reduced operational risk for research workflows.

Pluto further strengthens reproducibility through isolated package environments and exact version pinning embedded within every notebook. Stored as standard .jl source files, notebooks support clean version control, direct execution and easier collaboration than JSON-based notebook formats. Developed alongside MIT's Computational Thinking course, Pluto has gained adoption across computational biology, physics, climate science and data science education. Available under the MIT License, the project's 1.0 release lowers barriers to institutional deployment, curriculum development and research infrastructure adoption.
