

Grafana Pyroscope: An Open Source Continuous Profiling Tool

production environments with very little overhead, enabling businesses to identify regressions in performance, maximise resource use, and enhance application dependability. The technology, which was first created by Pyroscope and then purchased by Grafana Labs, is now an essential part of contemporary observability platforms.

What is continuous profiling?

Continuous profiling is the process of continuously collecting performance data from applications while they are running. It enables teams to:

- Detect CPU bottlenecks
- Identify memory leaks
- Analyse code execution paths
- Track performance regressions
- Reduce cloud infrastructure costs

With its advanced architecture, Grafana Pyroscope enables organisations to identify CPU hotspots, memory leaks, inefficient code paths, lock contention issues, and performance regressions with remarkable precision.

Grafana Pyroscope is an open source continuous profiling platform designed to help developers, system administrators, DevOps engineers, and site reliability engineers (SREs) identify performance bottlenecks in applications and infrastructure. It allows users to see how CPU,

memory, and other resources are being used over time by continuously gathering profile data from active applications and storing it for long-term analysis. Conventional profiling tools are sometimes limited for use in development or troubleshooting sessions. Pyroscope, on the other hand, continuously profiles applications in
