

Built on open, enterprise-grade platforms such as Red Hat OpenShift and Red Hat AI, the platform positions open source as the foundation for digital sovereignty, enabling portability, interoperability, and avoidance of vendor lock-in across hybrid and sovereign environments.

IBM Sovereign Core marks a strategic shift from policy-based sovereignty to runtime enforcement, embedding continuous compliance, auditability, and governance directly into operations. Its unified architecture integrates control plane, identity, security, compliance, and AI execution within a single deployment model.

Key capabilities include a customer-operated control plane, in-boundary encryption and data services, continuous compliance monitoring with automated evidence generation, preloaded regulatory frameworks, and governed AI execution ensuring full control over model inference, lifecycle, and traceability.

“AI has made sovereignty a runtime requirement, not a policy statement. With IBM Sovereign Core, organisations don’t have to choose between deploying AI at speed and verifying their control. Sovereignty shouldn’t be a constraint on innovation — with the right software foundation, it’s an enabler of it,” said Dinesh Nirmal, SVP, IBM Software. The platform supports an open ecosystem spanning AMD, Intel, Dell, MongoDB, Cloudera, and others, enabling enterprises, governments, and service providers to deploy compliant sovereign AI environments at scale.

Microsoft releases the 86-DOS 1.00 source code on GitHub to preserve computing history

Microsoft has open sourced the source code for 86-DOS 1.00 on GitHub, marking the 45th anniversary of the software and positioning the move as a digital preservation effort rather than a push for modern development.

The release carries deep historical significance. 86-DOS 1.00 served as the direct ancestor of MS-DOS and, by extension, Windows, and later formed the foundation of PC-DOS, which was licensed to IBM.

Originally developed by Tim Paterson, 86-DOS was acquired by Bill Gates and Microsoft for approximately \$75,000 from Seattle Computer Products. Following modifications, it was delivered as PC-DOS 1.0 in August 1981.

The open sourced material includes the 86-DOS 1.00 kernel, development snapshots of the PC-DOS 1.00 kernel, utilities such as CHKDSK, and even assembler listings and related tools, offering a rare, low-level view into early operating system development.

Microsoft stated that the release is intended to support study, preservation, and exploration of computing history. In its blog, the company noted: “Software history lives in code, yes, but also in scanned listings, internal documents, assembler printouts, and the sometimes wonderfully analogue artifacts of how operating systems came together in the late 1970s and early 1980s.”

The archival effort was supported by a team led by Yufeng Gao and Rich Cini, who worked to locate, scan, and transcribe original DOS-era materials.

Microsoft had previously open sourced MS-DOS versions 1.25, 2.11, and 4.0, reinforcing its evolving approach to legacy software transparency.

GitHub Actions workflow flaw leads to security breach

A supply-chain attack has compromised the open source Python package element-data, which records more than 1 million monthly downloads, after attackers exploited a flaw in the project’s GitHub Actions workflow to push a malicious release.

The tainted version, 0.23.3, was uploaded to PyPI and Docker and designed to harvest sensitive data, including cloud keys, API tokens, SSH keys, warehouse credentials and .env secrets. The malicious package remained available for about 12 hours before being removed.

Immudb 1.11 ensures unalterable audit trails and simplified compliance

Codenotary has launched immudb 1.11, a major update to its open source database that advances it from a tamper-proof datastore into a full trust infrastructure layer. The release introduces immutable audit logging built directly into immudb, enabling organisations to create permanent, tamper-proof records of both data and database activity, including who accessed or modified data and when.

Built on cryptographic verification, immudb ensures that neither data nor its history can be altered or deleted without detection. This architectural shift removes the need for external logging tools, consolidating all records within a single system and eliminating risks associated with fragmented or modifiable logs.

The update also delivers compatibility with PostgreSQL, allowing existing applications and tools to run unchanged while gaining built-in immutability and auditability. This lowers migration barriers and expands adoption across enterprise environments.

For organisations, the result is unalterable audit trails, simplified compliance and reporting, and reduced operational complexity. By embedding auditability as a native capability, immudb positions open source as a credible alternative to proprietary compliance and logging systems.

“The new immudb focuses on a problem many organisations struggle with: proving that their data – and the actions taken on it – can be trusted,” said Dennis Zimmer, co-founder and chief technology officer, Codenotary. “While most systems rely on separate logging tools to track changes, those logs can be incomplete, disconnected, or even altered.”
