

on how to compete meaningfully. We identified two priorities: first, helping customers actually adopt AI by building real, usable use cases; and second, deciding what we would leverage to build those capabilities.

Our answer was to combine three core strengths: GPU infrastructure we own, open source and open-weight models comparable to today's frontier models, and Indian engineering talent. The M platform is built on this foundation, making it inherently sovereign. It brings together Indian-owned GPUs, open source AI, and local talent to deliver practical AI solutions. M functions as a common platform that hosts multiple AI use cases under a single interface.

Q. What kinds of applications run on M today?

A. M is a multi-agent platform. For example, we are working with InterGlobe Technology Quotient (ITQ) using Travelport data, which covers bookings across 400 airlines and over 650,000 hotels, to reimagine travel experiences with AI. We have also onboarded Indian open source models, including language and domain-specific models.

Q. Is M trying to compete with ChatGPT, DeepSeek, or other frontier models?

A. Competing head-on with ChatGPT isn't the goal, you can't beat free with free. M is built for utility, not generic conversation, with a sharp focus on India-specific needs. Unlike global, general-purpose models, M offers deep contextual understanding of Indian law, finance, language, and workflows. At its core, M is agent-driven. A single interface understands user intent and routes each query to the most relevant domain-expert model, enabling task execution rather than just dialogue.

Key examples include an Indian legal model trained on all Indian laws and court judgments from 1969 to September this

year, aimed at helping citizens understand real-world legal rights, with endorsement being sought from the Ministry of Law. M also features a financial assistant capable of answering queries at a chartered-accountant level, with plans to support actions like income-tax filing. Overall, M stays practical, India-centric, and purpose-built rather than competing as another chatbot.

Q. What does the name 'M' signify?

A. Alphabet letters cannot be copyrighted, which makes them globally usable. Philosophically, 'M' represents the first sound a human makes at the beginning of interaction with the world. That symbolism resonated with us as the starting point of human intelligence and communication.

Q. How central is open source to the M platform?

A. Open source powers everything (of M) from frontend to backend. None of the core components are proprietary. This allows us to continuously adopt the best models for reasoning, coding, or specific tasks. Instead of being locked into one model's limitations, we curate the best tools available. Where required, we fine-tune and domain-adapt models for Indian contexts. This approach dramatically reduces cost and accelerates innovation.

Q. Can developers contribute to M? How does the community engage?

A. Yes. Contributions happen via GitHub and through communities embedded in our portal. The strongest engagement today is around our coding agent, which integrates directly into IDEs like Visual Studio. Developers contribute feedback, improvements, and testing insights. We also collaborate globally through forums such as the AI Alliance, exchanging knowledge and best practices across borders.

Q. There is growing concern that open source AI can be misused. What is your view?

A. AI is like electricity; it should belong to everyone. While open source can be misused, the real constraint isn't code but compute, which is scarce and tightly controlled. Running AI at scale requires significant infrastructure, making unrestricted misuse difficult. AI is already being weaponised, but not because of open source alone. The bigger risk is global polarisation, where a few countries, mainly the US and China, dominate AI, while most of the world is left behind.

With only around 20–22 countries having meaningful GPU capacity, the rest risk becoming digital colonies of powerful governments or corporations. Open source, combined with sovereign AI infrastructure, is one of the few ways to democratize capability and prevent this imbalance.

Q. Has the government supported your AI initiatives?

A. We didn't seek government support for M because building it isn't overly complex. Our engagement with the government is more focused on specific problem statements, such as AI-driven cybersecurity. Traditional GenAI models struggle here due to limited context windows, while cybersecurity analysis involves millions of logs at a time.

We have applied for India AI Mission grants to address this challenge, though approvals are still pending.

More broadly, our role today is as a GPU provider, supporting multiple initiatives being built on that infrastructure. M itself doesn't depend on government backing, but for consumer adoption, the real challenge is delivering a seamless, world-class experience, something as intuitive and frictionless as WhatsApp before taking it to scale.
