

MOON DUST

The Moon is silvery grey, without the Earth's green patches of plant life. There is no liquid water, or atmosphere (gas layer) to block out harmful radiation and provide the gases a plant needs to survive. However, Moon dust is similar to soil.

Moon dust

There are no living things to create tiny tunnels and caverns in Moon dust. On Earth, water, nutrients, and gases move through these spaces for plants to absorb.

Moon dust is mainly tiny bits of glass.

Craters are formed when large meteors hit the Moon.

Moon rock forms from lava cooling on the surface.

True soil

Soil needs living things. These eventually form the organic matter inside it, as well as its structure. Even if you added water to Moon dust, it would just form a paste.
