

MEAT-EATER!

A meat-eater's digestive system, shown by this *Carnotaurus*, was similar to that of reptiles we know today, such as crocodiles. Compared to those of a plant eater, the intestines are small, while the liver is large. The heart and lungs are also large, because the dinosaur would have needed extra oxygen to run after its prey.

▲ **CARNOTAURUS** Fossils show that many meat-eating dinosaurs had hollows in their bones, which may have been air spaces. These might have allowed an increased oxygen flow to the lungs, helping these dinosaurs to be active.
