

A FOUR-WINGED DINOSAUR?

Microraptor had long, bird-style flight feathers on its arms and legs, giving it what seem to be four wings. How it used these is a mystery. Some scientists suggest it could spread out its hind legs when gliding, but its hip joints may not have had enough flexibility to do this.

◀ FEATHERED FOSSIL

This well-preserved fossil shows impressions of long feathers on the arms and legs. A stiff tail, typical of a dromaeosaur, is also visible.
