

◀ CHANGING COLORS

Studies of Marrella fossils suggest that its surface was iridescent, meaning that it had a colorful sheen that glinted and changed color as the light moved, like the surface of a soap bubble or a butterfly's wings.

▲ PRESERVED IN MUD

More than 15,000 fossils of Marrella have been found, all of them at one location in Canada. The fossils are in a type of rock called shale, formed from seafloor mud.
